## What is Breast Thermography?

Breast Thermography is a painless, non invasive, state of the art clinical test without any exposure to radiation (ionizing) and is used as part of an early detection program which gives women of all ages the opportunity to increase their chances of detecting breast disease at an early stage. It is particularly useful for women under 50 where mammography is less effective. It is also FDA approved.

Thermography is a diagnostic technique that converts infrared radiation (non-ionizing) emitted from the skin surface into electrical impulses that are visualized in color.

Breast Thermography's major clinical value is in its high sensitivity to pathology in the vascular, muscular, neural and skeletal systems. This test is designed to improve chances for detecting fast-growing, active tumours in the intervals between mammographic screenings or when mammography is not indicated by breast screening guidelines.

All patient's thermograms (breast images) are kept in secure records that form a baseline for all future routine evaluations and comparisons. It takes years for a tumour to grow, and the earliest possible indication of an abnormality is needed to allow for the earliest possible treatment and intervention to occur.

Regular screening can provide an early alert for *possible* referrals to mammography, ultrasound, MRI or further testing to improve early detection by your doctor. *Neither Mammogram, Ultrasound, nor Breast Thermography can diagnose breast cancer- only a biopsy can.*

Thermography is safe for all ages and life stages. It is also safe in Pregnancy. The readings are unaffected by breast types including: dense, hormonally induced and breasts with implants. Women self refer to this service.

Thermography Reports are generated by a group of expert medical doctors that are board certified thermologists by the American College of Clinical Thermology. Your health care provider has direct access to these resources for consultation.
